MetRe: Supporting the Metadata Revision Process

Introduction

MetRe is a prototype interface and service designed to support the metadata revision process. Improving the consistency of metadata records within an environment is a common repository management task, not only because of the potential for user error when submitting, but also because of other sources of error, such as systematic error resulting from the limitations of the deposit process chosen. Evidence to support the metadata correction process may be provided by automated metadata extraction tools, evidence from within the repository, or by comparison with best practice across the repository landscape.

Functionality

This prototype is able to identify several characteristic classes of error, twinned with an interface able to highlight several types of individual and systematic error, including a notion of local and general best practice. These may be used in a variety of ways – for ranking in priority order, for browsing or correcting systematic error according to symptom, or directly editing a single record via an AJAX-based customised form. The approach makes use of statistical information gleaned from local (intra-repository) and global (inter-repository) harvested metadata to identify patterns, rank occurrences and co-occurrences.

Service architecture for the MetRe prototype

Exploring metadata consistency via the MetRe prototype

The role of the metadata registry

Pragmatically, the development of 'spelling, grammar and consistency' checkers for metadata is rendered simpler by the existence of machinereadable entity, metadata element and structural definitions, as well as generalpurpose service APIs for 'sanity-checking' against other sources. These may include anything from information available on the Web to formal metadata to be extracted from the data object itself, in the event that this is practically achievable. It is therefore in part the increasing availability of such resources as easy-to-access Web services that makes services employing this information relatively practical to develop and to maintain. In the case of MetRe, the IEMSR metadata schema registry is a core component.

Functionalities for automatic metadata generation applications: a survey of metadata experts' opinions. Int J. Metadata, Semantics and Ontologies 2006, 1(1), 2006. L. Swartz. Why People Hate the Paperclip: Labels, Appearance, Behavior, and Social Responses to User Interface Agents. Master's thesis, Stanford University, California, 2003. E. Tonkin and H. Muller. Semi automated metadata extraction for preprints archives. In Proceedings of the 8th ACM/IEEE-CS joint

conference on digital libraries, 2008.

Evaluation.

We chose to evaluate the prototype on an intra-repository task, primarily because we felt that this would require less knowledge of general metadata practice, and would allow us to work within a familiar interface and environment as well as a familiar application profile. We built the prototype interface by customising a DSpace page via JavaScript, which interfaces to the MetRe service via a local proxy. Initial user testing of the prototype shows that it is quick and simple to use by comparison to manual editing without assistance, which requires a good knowledge of Dublin Core metadata and reveals itself to be a frustrating task.

Future work.

In future, we plan to:

- develop the system further,
- complete more user testing in a production environment.
- increase the number of types of error or warning that are recognised,
- to make future tools available as a publicly accessible service for general use.

This work will be continued within the JISCfunded FixRep project, which will explore integration of a variety of services and methods into a basic framework similar to that described here.

UKOLN, University of Bath, UK

Consistency

"Use of recommended or mandated structures, schemes or policies which might enable software designers and service creators to predict with some certainty the type of content to expect." – Definition (Charlesworth et al, 2008)

"Inconsistency is a fact of life, and any repository instance or system that wants to avoid bottlenecks is going to have to accept items that have inconsistent metadata [...] That doesn't mean you have to settle for it, though. It's possible to take a progressive approach, where messy metadata comes in, and is then brought into consistency with particular standards."

(Charlesworth et al, 2008)
